Homework1

Jack Cheng 8/6/2017

R Markdown

This is the homework 1 for the second part of STA380 in Red McCombs business school.

Statistics Questions:

Question 1

From the question we know that:

P(RC)=0.3

P(TC)=1-P(RC)=0.7 since TC is the complement of RC

P(Y) = 0.65

P(Y|RC)=0.5

Where RC denotes that the clicker is a random clicker, TC denotes the clicker is a truthful clicker and Y denotes the result is yes.

And we want to know P(Y|TC).

Solution:

P(Y,RC)=P(Y|RC)*P(RC)=0.5*0.3=0.15

P(Y,TC)=P(Y)-P(Y,RC)=0.65-0.15=0.5 since TC is the complement of RC

so P(Y|TC)=P(Y,TC)/P(TC)=0.5/0.7=0.7142857

Question 2

From the question we know that:

P(P|D) = 0.993

P(N|Dc)=0.9999

P(D)=0.000025

Where D denotes with desease, Dc denotes no desease, P denotes positive and N denotes negative.

We want to know: P(D|P)

Solution:

since we know Dc is the complement of D

so P(Dc)=1-P(D)=0.999975 and P(P)=P(Dc,P)+P(D,P)

and N is the complement of P

so P(P|Dc)=1-P(N|Dc)=0.0001

```
\begin{split} &P(D|P) \! = \! P(D,P)/P(P) \\ &= \! (P(P|D)^*P(D))/(P(D,P) \! + \! P(Dc,P)) \\ &= \! (P(P|D)^*P(D))/(P(P|D)^*P(D) \! + \! P(Dc,P)^*P(Dc)) \\ &= \! 0.993^*0.000025/(0.993^*0.000025 \! + \! 0.0001^*0.999975) \! = \! 0.1988824 \end{split} Which is really high!
```

That is to say though the sensitivity and specificity of the test is really good, due to the fact that the prior probability of desease is so low as 0.000025, the false positive rate is still really high. This kind of implementing a universal testing policy for the disease will lead to panic and chaos.

Exploratory analysis: green buildings

```
green_house = read.csv("~/Desktop/UT Austin/Predictive learning/greenbuildings.csv")
green_only = subset(green_house, green_rating==1)
green.rent=rep(NA,length(unique(green house$cluster)))
avg.rent = rep(NA,length(unique(green_house$cluster)))
for (i in 1:length(unique(green_house$cluster))){
  index = which(green_house$cluster==unique(green_house$cluster)[i])
  green.rent[i]=green_house$Rent[index]
  avg.rent[i]=green_house$cluster_rent[index]

              2007-2017
                                                 2007-2017
```

First let us just to explore the data by looking at the mean and variance of each asset to get a roughly idea about their risk return properties:

boxplot(all_returns,outline=FALSE,col=rainbow(5),ylab='Return')

library(plotly)

```
##
## Attaching package: 'plotly'
##
  The following object is masked from 'package:mosaic':
##
##
       do
  The following object is masked from 'package:ggplot2':
##
##
##
       last_plot
##
  The following object is masked from 'package:stats':
##
##
       filter
  The following object is masked from 'package:graphics':
##
##
       layout
plot_ly(type='box', yaxis= list(range = c(-0.5, 0.5))) %>%
  add_boxplot(y = all_returns[,3], name = 'SPY') %>%
  add_boxplot(y = all_returns[,4], name = 'TLT') %>%
  add_boxplot(y = all_returns[,2], name = 'LQD') %>%
  add_boxplot(y = all_returns[,1], name = 'EEM') %>%
  add_boxplot(y = all_returns[,5], name = 'VNQ') %>%
 layout(
   yaxis = list(range = c(-0.5,0.5)))
```

We can see through the graph that EEM and VNQ are with high volatility and rather high return and the TLT is just the most robust way of investing. Then let us see the sharp ratio for those assets first to get a more through measurement of these assets:

• There are many ways to measure the performance of a certain asset. Here we choose the sharp ratio, Jensen's alpha and treynor ratio as examples.

Note that sharp ratio is the ratio between extra mean return exceed risk free asset and the volitility of asset.

First use TLT as an approximation to the risk free asset. Calculate the extra return of each asset:

```
EEMa = adjustOHLC(EEM)
LQDa = adjustOHLC(LQD)
SPYa = adjustOHLC(SPY)
TLTa = adjustOHLC(TLT)
VNQa = adjustOHLC(VNQ)
EEM_extra_return=all_returns[,1]-all_returns[,4]
LQD extra return=all returns[,2]-all returns[,4]
Market_extra_return=all_returns[,3]-all_returns[,4]
VNQ extra return=all returns[,5]-all returns[,4]
EEM_SD=sd(EEM_extra_return)
LQD_SD=sd(LQD_extra_return)
Market_SD=sd(Market_extra_return)
VNQ_SD=sd(VNQ_extra_return)
SR_EEM=mean(EEM_extra_return)/EEM_SD
SR_LQD=mean(LQD_extra_return)/LQD_SD
SR_Market=mean(Market_extra_return)/Market_SD
SR_VNQ=mean(VNQ_extra_return)/VNQ_SD
SR_EEM
## [1] 0.01669493
SR_LQD
## [1] -0.009391961
SR Market
## [1] 0.002428866
SR_VNQ
```

[1] 0.0046315

Actually here we see that LQD have a lower mean return than risk free asset, that probably suggest us not to invest in this asset since this performance is really terrible. EEM got the highest sharp ratio.

Then we look at Jensen's alpha:

Jensen's alpha is a measurement of the return after adjusting by taking risk into account.

Fit the data with a CAPM model first:

```
lmEEM=lm(EEM_extra_return~Market_extra_return)
lmLQD=lm(LQD_extra_return~Market_extra_return)
lmVNQ=lm(VNQ_extra_return~Market_extra_return)
coef(lmEEM)

## (Intercept) Market_extra_return
## 0.000688956 1.184530681

coef(lmLQD)

## (Intercept) Market_extra_return
## -9.757413e-05 3.552796e-01
```

```
coef(lmVNQ)
##
            (Intercept) Market_extra_return
          6.770747e-05
                                1.157167e+00
##
The alpha and beta are intercept and beta in this particular case.
We can see that EEM get the highest alpha while VNQ get the lowest.
Then let us look at the treynor ratio:
TR_EEM=mean(EEM_extra_return)/coef(lmEEM)[2]
TR_LQD=mean(LQD_extra_return)/coef(lmLQD)[2]
TR VNQ=mean(VNQ extra return)/coef(lmVNQ)[2]
TR_EEM
## Market_extra_return
          0.0006276331
TR_LQD
## Market_extra_return
         -0.0002286351
##
TR_VNQ
## Market extra return
```

We can see here that EEM is with the highest treynor ratio.

Now we begin the boostrapping simulation.

0.0001045167

The even split one

##

```
set.seed(888)
initial_wealth = 10000
sim1 = foreach(i=1:500, .combine='rbind') %do% {
   total_wealth = initial_wealth
   weights = c(0.2, 0.2, 0.2, 0.2, 0.2)
   holdings = weights * total_wealth
   n_{days} = 20
   wealthtracker = rep(0, n_days)
   for(today in 1:n_days) {
        return.today = resample(all_returns, 1, orig.ids=FALSE)
        holdings = holdings + holdings*return.today
        total_wealth = sum(holdings)
        wealthtracker[today] = total_wealth
   }
    wealthtracker
}
mean(sim1[,n_days] - initial_wealth)
## [1] 99.38072
```

```
## [1] 99.38072
hist(main = 'The even split portfolio return', sim1[,n_days] - initial_wealth, breaks=30)
```

The even split portfolio return

The safer portfolio Next we have our safe portfolio as we invest more on the TLT and since we analysis that LQD is inefficient so we do not invest in it.

```
set.seed(888)
initial_wealth = 10000
sim2 = foreach(i=1:500, .combine='rbind') %do% {
    total_wealth = initial_wealth
    weights = c(0.1, 0, 0.1, 0.7, 0.1)
    holdings = weights * total_wealth
    n_days = 20
    wealthtracker = rep(0, n_days)
    for(today in 1:n_days) {
        return.today = resample(all_returns, 1, orig.ids=FALSE)
        holdings = holdings + holdings*return.today
        total_wealth = sum(holdings)
        wealthtracker[today] = total_wealth
    }
    wealthtracker
}
mean(sim2[,n_days]- initial_wealth)
```

```
## [1] 87.44794
hist(main = 'The safer portfolio return',sim2[,n_days]- initial_wealth, breaks=30)
```

The safer portfolio return

The more aggressive one.

In this one we choose to invest in more EEM which is a more risky asset.

```
set.seed(888)
initial_wealth = 10000
sim3 = foreach(i=1:500, .combine='rbind') %do% {
    total_wealth = initial_wealth
    weights = c(0.6, 0, 0.1, 0.1, 0.1)
    holdings = weights * total_wealth
    n_{days} = 20
    wealthtracker = rep(0, n_days)
    for(today in 1:n_days) {
        return.today = resample(all_returns, 1, orig.ids=FALSE)
        holdings = holdings + holdings*return.today
        total_wealth = sum(holdings)
        wealthtracker[today] = total_wealth
    }
    wealthtracker
mean(sim3[,n_days] - initial_wealth)
```

[1] -845.7464

The more aggressive portfolio return

sim3[, n_days] - initial_wealth

Now let us

look at the value at risk at 5% level of these portfolios:

```
quantile(sim1[,n_days], 0.05) - initial_wealth
##
          5%
## -635.7145
quantile(sim2[,n_days], 0.05) - initial_wealth
##
          5%
## -409.0383
quantile(sim3[,n_days], 0.05) - initial_wealth
##
          5%
```

-1961.649

As we can see, here we have the value at risk of 5% for these three different portfolio with different style, and these numbers make sence as the aggressive one have the highest risk and the safe one is with the lowest risk.

                                                                 10
                                                                          20
                          20
                                    30
                                                                                   30
                  number of K
                                                                  number of k
```

based on the graphs above, we are able to see the relationship between number of K and CH(K) and W(K) respectively. As the number of K increases, both values of CH(K) and W(K) decrease. Since we could only have 32 clusters for 32 variables, we tried different K from k=2 to k=32 and find out that CH(K) and W(K) are at minimum when K=32. However, this does not make sense to us since K=32 is too large and we would have same variables in different clusters.

K means for k=2 to k=8

After we look at the k mean ++ method, we concluded that when k = 5, the clustering result makes more
sense to us. So we decided to go with this result.

We tried heluster for k=5 for min, max and average methods and find out that heluster does not work very well in this case because most of the data points lie on cluster 1.

So we just give up using this heluster model due to its significantly inbalance cluster result that obviously will not work for the user segmentation task.
